In this report, simultaneous SAXS and WAXS were used to investigate the crystal transformation and lamellar variation of the electrospun Nylon 6 nano-fibers with a diameter of 200 nm during step-wise heating. The results were compared with those obtained from the solution cast Nylon 6 film with a thickness of $\sim 10\ \mu\text{m}$.

Fig. 1: (a) WAXD intensity profiles of electrospun Nylon 6 fibers at selected annealing temperature T_a from 30 to 220°C, (b) SAXS intensity profiles (Lorentz-corrected plot) of the electrospun fibers at the corresponding T_a .

As shown in Fig. 1, the as-spun Nylon 6 fibers possess the mixed crystal modifications of α -form ($2\theta = 20.61^\circ, 23.36^\circ$) and γ -form ($2\theta = 10.73^\circ, 21.41^\circ$) in the absence of regular lamellar spacing. No significant variation of the WAXD and SAXS intensity profiles are seen for an annealing temperature (T_a) of 50°C. At $T_a = 75\sim 140^\circ\text{C}$, the amount of α -form is slightly reduced and a barely-seen SAXS hump is detected ($q_{\text{max}} = 0.0946\ \text{\AA}^{-1}$), suggesting the gradual development of ordered lamellae during heating. In the temperature range of $140\sim 180^\circ\text{C}$, no crystal melting takes place, but the SAXS peak becomes pronounced and slightly shifts to the low q region ($q_{\text{max}} = 0.0783\ \text{\AA}^{-1}$), indicating the increase of the lamellar thickness. For T_a above 200°C , some γ -form crystals start to melt, and the position of SAXS peak shifts pronouncedly towards a low q region, indicating the rapid increase of the lamellar spacing. The long period is ca. $126\ \text{\AA}$ at $T_a = 210^\circ\text{C}$. The diffraction peak at $2\theta = 10.73^\circ$, which is the fingerprint of strong orientation of γ -form, finally disappears at 210°C . At $T_a = 220^\circ\text{C}$, featureless structure is detected from the WAXD and SAXS scattering.

Fig. 2: (a) WAXD intensity profiles of solution-cast Nylon 6 films at selected annealing temperature T_a from 40 to 220°C, (b) SAXS intensity profiles (Lorentz-corrected plot) of the solution-cast film at the corresponding T_a .

Solution-cast films possess the α -form crystals with a SAXS peak at $0.0776\ \text{\AA}^{-1}$ at 40°C . On heating, the two WAXS diffraction peaks ($2\theta = 20.42^\circ, 23.60^\circ$) move closer to each other with a gradual reduction of the peak intensity. At 210°C , the two WAXD diffraction peaks are located at 20.89° and 21.81° . At 220°C , all the crystals are melted away and only the amorphous halo ($2\theta = 19.84^\circ$) is seen. According to the T_a -dependence of SAXS intensity profiles, it is evident that q_{max} remains intact for $T_a < 140^\circ\text{C}$. For $T_a > 160^\circ\text{C}$, q_{max} gradually moves to the low q region and simultaneously the intensity of SAXS peak is also increased until $T_a = 200^\circ\text{C}$. At 210°C , a large long period of $164\ \text{\AA}$ is reached but the intensity is reduced due to the occurrence of major crystal melting, as-revealed by WAXD intensity profile. Based on Fig. 2, it is concluded that no $\alpha \rightarrow \gamma$ crystal transformation takes place, but a gradual melting of the α -form crystals together with the lamellar thickening occurs during step-wise annealing of the solution-cast Nylon 6 film.
